

Task 1
Merge
(Birlash)

Ikki yoki undan ortiq jadvallarni mos keluvchi ustunlar (masalan, ID) bo'yicha **ustunlar orqali birlashtiradi**. Bu SQL dagi **JOIN** amaliyotiga o'xshaydi.

Append
(Qo'shish)

Ikki yoki undan ortiq jadvallarni **qatorlar bo'yicha birlashtiradi**, ya'ni ma'lumotlarni ustunlar bir xil bo'lsa, pastga qarab birga qo'shadi. Bu SQL dagi **UNION** amaliyotiga o'xshaydi.

Task 2

Using "Split Column" by Delimiter

1-usul: "Split Column" funksiyasidan bo'luvchi orqali foydalanish

1. Open Power Query Editor (in Excel or Power BI).

Power Query tahrirlovchisining oynasini oching (Excel yoki Power BI ichida).

2. Select the `Full Name` column.

`Full Name` ustunini tanlang.

3. Go to the Home or Transform tab.

Yuqori menyudan Home yoki Transform bo'limiga o'ting.

4. Click Split Column → By Delimiter.

Split Column → By Delimiter tugmasini bosing.

5. Choose Space as the delimiter.

Bo'luvchi sifatida Space (bo'sh joy) ni tanlang.

6. Under Split Into, choose:

Split Into bo'limida:

- Each occurrence of the delimiter (for middle names), or

Bo'luvchi har bir uchragan joyda ajratish (otasining ismi bor bo'lsa),

- At the first occurrence (to just split into first and last name).

Yoki faqat birinchi bo'sh joydan ajratish (ism va familiyani olish uchun).

7. Click OK.

OK tugmasini bosing.

This will create two columns:

Bu amal natijasida ikki ustun hosil bo‘ladi:

- `Full Name.1 = First Name`

`Full Name.1 – Ism`

- `Full Name.2 = Last Name (or remaining)`

`Full Name.2 – Familiya (yoki qolgan qism)`

You can then rename them to `First Name` and `Last Name`.

Ularni `First Name` va `Last Name` deb nomlashingiz mumkin.

Method 2: Use Power Query Formula (Advanced)

2-usul: Power Query formulasidan (ilgor usul) foydalanish

If you want more control or the delimiter varies, you can add custom columns.

Agar ko‘proq nazorat qilishni istasangiz yoki bo‘luvchi turlicha bo‘lsa, qo‘shimcha ustunlar qo‘shishingiz mumkin.

Example using M code:

M kodi misoli:

```
= Table.AddColumn(YourPreviousStep, "First Name", each  
Text.BeforeDelimiter([Full Name], " "))  
= Table.AddColumn(PreviousStep, "Last Name", each Text.AfterDelimiter([Full  
Name], " "))
```

Task 3

“Pivot Columns” ustunlarni satrga aylantirish (jadvalni qayta tuzish) uchun ishlatiladi. Bu yordamida ma’lumotlarni tahlil qilish va ko‘rinishini o‘zgartirish osonlashadi.

Task 4

Power Query’da bir qadamni bekor qilish uchun **Applied Steps** oynasidan o‘sha qadamni topib, yonidagi “X” belgisini bosasiz. Shunda o‘sha qadam bekor qilinadi

Task 5

- **Reference** — mavjud so‘rovga yangi bog‘langan so‘rov yaratadi. Ya’ni, yangi so‘rov asl so‘rovga ulanadi va o‘zgarishlar asos so‘rovga ta’sir qilmaydi, lekin asl ma’lumot manbasi bilan bog‘langan.

- **Duplicate** — mavjud so‘rovning to‘liq nusxasini yaratadi. Yangi so‘rov mustaqil bo‘lib, undagi o‘zgarishlar asl so‘rovga ta’sir qilmaydi.

Task 6

- **Power Query Editor** oynasini oching.
- Jadvalingizda **Product** ustunini tanlang.
- Yuqori menyudan **Transform** tabiga o‘ting.
- **Pivot Column** tugmasini bosing.
- **Values Column** sifatida **Quantity** ustunini tanlang.
- Aggregation (jamlash) usulidan **Sum** (yig‘indi) ni tanlang.
- OK tugmasini bosing.

Task 11

let

```
JoinType = "Inner", // Parametr sifatida foydalanilmoqda
```

```
Table1 = YourFirstQuery,
```

```
Table2 = YourSecondQuery,
```

```
JoinKind =
```

```
    if JoinType = "Inner" then JoinKind.Inner
```

```
    else if JoinType = "LeftOuter" then JoinKind.LeftOuter
```

```
    else if JoinType = "RightOuter" then JoinKind.RightOuter
```

```
    else if JoinType = "FullOuter" then JoinKind.FullOuter
```

```
    else JoinKind.Inner, // Default qiymat
```

```
MergedTable = Table.NestedJoin(Table1, {"CustID"}, Table2, {"CustID"}, "NewTable",  
JoinKind),
```

```
ExpandedTable = Table.ExpandTableColumn(MergedTable, "NewTable",  
Table.ColumnNames(Table2))
```

in

ExpandedTable

Task 12

- **Power Query Editor** oynasini oching.
- Unpivot qilmoqchi bo'lgan ustunlarni (masalan, Jan_Sales, Feb_Sales va boshqalar) tanlang.
- Yuqori menyudan **Transform** bo'limiga o'ting.
- **Unpivot Columns** tugmasini bosing.
- Natijada ikkita yangi ustun hosil bo'ladi:
 - **Attribute** (ustun nomlari) — bu yerda Jan_Sales, Feb_Sales kabi qiymatlar bo'ladi.
 - **Value** — bu yerda mos keluvchi qiymatlar bo'ladi.
- **Attribute** ustunining nomini Month deb o'zgartiring.
- **Value** ustunining nomini Sales deb o'zgartiring.

Task 13

= Table.AddColumn(OldingiQadam, "Natija", each try [Son1] / [Son2] otherwise null)

Task 14

(phone as text) as text =>

Text.Replace(phone, "-", "")

m

= Table.AddColumn(OldQuery, "CleanPhone", each CleanPhone([PhoneColumn]))
